

# Probability and Statistics with R

## Assignment 2

Submission Nov 16-2022 (Wednesday)

**Note:** Below I explain how you collaborate on GitHub.

1. It will be group assignment.
2. A group would be of size at most 3. If you want to create a group size more than 3, you must take permission.
3. Decide among yourself and one of you create a GitHub repository for Probability Statistics Assignments.
4. In that repository add your group members as collaborator
5. Once you add your collaborator (or group members), create a folder and name it as **Assignment\_2**
6. In that folder you should have 2 folders **code** and **report**. And one **README.md** file. Write a brief report in **README.md** file.
7. For each problem, you should create a separate GitHub **issue**. All your discussion should be documented in the **issue**.
8. In the issue mention clearly, which group member is taking ownership of what problem?
9. The other member should **fork** the repository in their GitHub account.
10. Once you have your forked the main repository in your GitHub account - you should clone the repository in you local laptop or just download it as zip.
11. Once you develop the code - you should **commit** the code first in your repository and then **push** it.
12. Finally you make the **pull-request** in the final repository.
13. Once a member make a pull request, the other members have to review the code.
14. While reviewing the code the reviewer may have to download the code and run the code in his or her system and reproduce the result.
15. If the result is reproduced then she or he would accept and merge the code in final repository.
16. At the end you submit the link of the repository in the moodle.
17. The entire process will be evaluated.

### Problem 1

Suppose  $X$  denote the number of goals scored by home team in premier league. We can assume  $X$  is a random variable. Then we have to build the probability distribution to model the probability of number of goals. Since  $X$  takes value in  $\mathbb{N} = \{0, 1, 2, \dots\}$ , we can consider the geometric progression sequence as possible candidate model, i.e.,

$$S = \{a, ar, ar^2, ar^3, \dots\}.$$

But we have to be careful and put proper conditions in place and modify  $S$  in such a way so that it becomes proper probability distributions.

Q1 Figure out the necessary conditions and define the probability distribution model using  $S$ .

A1 We need the following conditions for  $S$  to be a pdf:

1.  $0 \leq ar^n \leq 1 \quad \forall n$ .
2.  $\sum_{n=0}^{\infty} \mathbb{P}(X = n)$  converges to 1, hence we must have that  $r < 1$ .
3. Since  $\sum_{n=0}^{\infty} ar^n = \frac{a}{1-r}$  and using the above, we must have  $\mathbb{P}(X = n) = (1-r)r^n$ . (It is clear that  $X \sim \text{Geom}(1-r)$ )

Q2 Check if mean and variance exists for the probability model.

A2 Yes, they exist, since we know the mean and variance of Geometric random variable as done in class. we will derive them now.

Q3 Can you find the analytically expression of mean and variance?

1. Mean

$$\begin{aligned}
 E[X] &= \sum_{n=0}^{\infty} n \mathbb{P}(X = n) \\
 &= \sum_{n=0}^{\infty} n(1-r)r^n \\
 &= r \sum_{n=0}^{\infty} n(1-r)r^{n-1} \\
 &= r \sum_{n=1}^{\infty} (n-1)(1-r)r^{n-1} + r \sum_{n=1}^{\infty} (1-r)r^{n-1} \\
 &= rE[X] + r(1-r)\left(\frac{1}{1-r}\right) \\
 &= rE[X] + r
 \end{aligned}$$

$$\text{Hence, } E[X] = \frac{r}{1-r}$$

2. Variance

$$\begin{aligned}
 E[X^2] &= \sum_{n=0}^{\infty} n^2 \mathbb{P}(X = n) \\
 &= \sum_{n=0}^{\infty} n^2(1-r)r^n \\
 &= r \sum_{n=0}^{\infty} n^2(1-r)r^{n-1} \\
 &= r \sum_{n=1}^{\infty} (n-1)^2(1-r)r^{n-1} + \sum_{n=1}^{\infty} 2n(1-r)r^n - r \sum_{n=1}^{\infty} (1-r)r^{n-1} \\
 &= rE[X^2] + 2E[X] - r(1-r)\frac{1}{1-r} \\
 &= rE[X^2] + \frac{2r}{1-r} - r
 \end{aligned}$$

$$\text{Hence, } E[X^2] = \frac{r^2 + r}{(1-r)^2}. \text{ Therefore,}$$

$$\begin{aligned}
 \text{Var}(X) &= E[X^2] - (E[X])^2 \\
 &= \frac{r^2 + r}{(1-r)^2} - \frac{r^2}{(1-r)^2} \\
 &= \frac{r}{(1-r)^2}
 \end{aligned}$$

Q4 From historical data we found the following summary statistics Using the summary statistics and your

mean	median	variance	total number of matches
1.5	1	2.25	380

newly defined probability distribution model find the following:

1. What is the probability that home team will score at least one goal?

Ans

2. What is the probability that home team will score at least one goal but less than four goal?

Ans

Q5 Suppose on another thought you want to model it with off-the shelf Poisson probability models. Under the assumption that underlying distribution is Poisson probability find the above probabilities, i.e.,

1. What is the probability that home team will score at least one goal?

Ans

2. What is the probability that home team will score at least one goal but less than four goal?

Ans

Q6 Which probability model you would prefer over another?

A6

Q7 Write down the likelihood functions of your newly defined probability models and Poisson models.

A7

Clearly mention all the assumptions that you are making.

## Problem 2 : Simulation Study to Understand Sampling Distribution

**Part A** Suppose  $X_1, X_2, \dots, X_n \stackrel{iid}{\sim} \text{Gamma}(\alpha, \sigma)$ , with pdf as

$$f(x|\alpha, \sigma) = \frac{1}{\sigma^\alpha \Gamma(\alpha)} e^{-x/\sigma} x^{\alpha-1}, \quad 0 < x < \infty,$$

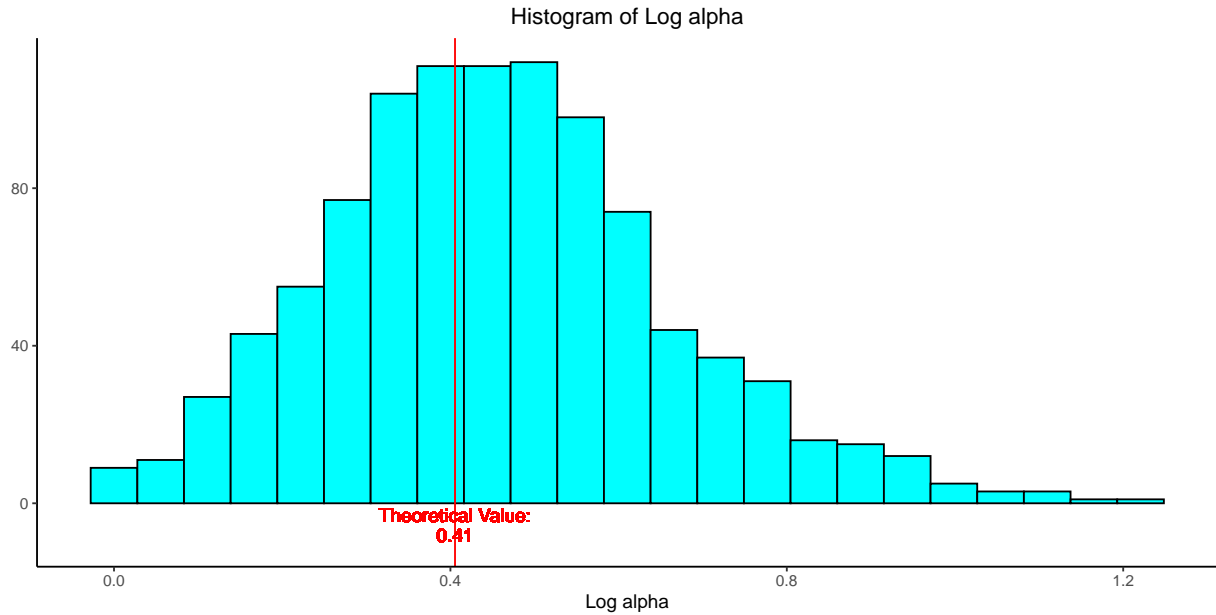

The mean and variance are  $E(X) = \alpha\sigma$  and  $\text{Var}(X) = \alpha\sigma^2$ . Note that **shape** =  $\alpha$  and **scale** =  $\sigma$ .

1. Write a function in R which will compute the MLE of  $\theta = \log(\alpha)$  using `optim` function in R. You can name it `MyMLE`
2. Choose `n=20`, and `alpha=1.5` and `sigma=2.2`
  - (i) Simulate  $\{X_1, X_2, \dots, X_n\}$  from `rgamma(n=20, shape=1.5, scale=2.2)`
  - (ii) Apply the `MyMLE` to estimate  $\theta$  and append the value in a vector
  - (iii) Repeat the step (i) and (ii) 1000 times
  - (iv) Draw histogram of the estimated MLEs of  $\theta$ .
  - (v) Draw a vertical line using `abline` function at the true value of  $\theta$ .
  - (vi) Use `quantile` function on estimated  $\theta$ 's to find the 2.5 and 97.5-percentile points.

```
## The 2.5th quantile is -0.03464124
## The 97.5th quantile is 1.134211
## The gap between the 2.5th and 97.5th quantile is 1.168852
```

3. Choose `n=40`, and `alpha=1.5` and repeat the (2).

```
## The 2.5th quantile is 0.09513601
## The 97.5th quantile is 0.9120567
## The gap between the 2.5th and 97.5th quantile is 0.8169207
```

4. Choose  $n=100$ , and  $\alpha=1.5$  and repeat the (2).

```
## The 2.5th quantile is 0.1852065
## The 97.5th quantile is 0.6778165
## The gap between the 2.5th and 97.5th quantile is 0.49261
```

5. Check if the gap between 2.5 and 97.5-percentile points are shrinking as sample size  $n$  is increasing.  
 Yes, the gap between the 2.5 and 97.5 quantiles is decreasing as we increase the sample size.

### Problem 3: Analysis of faithful datasets.

Consider the faithful datasets:

Fit following three models using MLE method and calculate **Akaike information criterion** (aka., AIC) for each fitted model. Based on AIC decides which model is the best model? Based on the best model calculate the following probability

$$\mathbb{P}(60 < \text{waiting} < 70)$$

(i) **Model 1:**

$$f(x) = p * \text{Gamma}(x|\alpha, \sigma_1) + (1 - p) * N(x|\mu, \sigma_2^2), \quad 0 < p < 1$$

```
## Optimal (p,alpha,sigma_1,mu,sigma_2) is 0.3652286 82.77782 0.661879 80.16515 5.809759
## AIC is 2076.18
```

(ii) **Model 2:**

$$f(x) = p * \text{Gamma}(x|\alpha_1, \sigma_1) + (1 - p) * \text{Gamma}(x|\alpha_2, \sigma_2), \quad 0 < p < 1$$

```
## Optimal (p,alpha_1,sigma_1,alpha_2,sigma_2) is 0.3708364 79.77377 0.6890328 199.2932 0.402859
## AIC is 2076.117
```

(iii) **Model 3:**

$$f(x) = p * \logNormal(x|\mu_1, \sigma_1^2) + (1 - p) * \logNormal(x|\mu_1, \sigma_1^2), \quad 0 < p < 1$$

```
## Optimal (p,alpha_1,sigma_1,alpha_2,sigma_2) is 0.3761462 4.003843 0.1148572 4.384302 0.06973756
## AIC is 2075.42
```

The AIC of the three models are 2076.18, 2076.117, 2075.42. Since AIC is a measure of information lost by a model, lower the AIC, better the model. So, given the data, Model 3 is the best fit for the data. We will use this model to predict  $\mathbb{P}(60 < X < 70)$ .

```
## [1] 0.09082032
```

## Problem 4: Modelling Insurance Claims

Consider the `Insurance` data sets in the `MASS` package. The data given in data frame `Insurance` consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

This data frame contains the following columns:

**District** (factor): district of residence of policyholder (1 to 4): 4 is major cities.

**Group** (an ordered factor): group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.

**Age** (an ordered factor): the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.

**Holders** : numbers of policyholders.

**Claims** : numbers of claims

**Note:** If you use built-in function like `lm` or any packages then no points will be awarded.

**Part A:** We want to predict the `Claims` as function of `Holders`. So we want to fit the following models:

$$\text{Claims}_i = \beta_0 + \beta_1 \text{Holders}_i + \varepsilon_i, \quad i = 1, 2, \dots, n$$

Assume :  $\varepsilon_i \sim N(0, \sigma^2)$ . Note that  $\beta_0, \beta_1 \in \mathbb{R}$  and  $\sigma \in \mathbb{R}^+$ .

The above model can also be re-expressed as,

$$\text{Claims}_i \sim N(\mu_i, \sigma^2), \quad \text{where}$$

$$\mu_i = \beta_0 + \beta_1 \text{Holders}_i + \varepsilon_i, \quad i = 1, 2, \dots, n$$

- (i) Clearly write down the negative-log-likelihood function in R. Then use `optim` function to estimate MLE of  $\theta = (\beta_0, \beta_1, \sigma)$
- (ii) Calculate **Bayesian Information Criterion** (BIC) for the model.

```
## [1] 0.1126414
```

```
## [1] 8.122018
```

```
## [1] 11.96235
```

```
## Optimal parameters are 8.120581 0.1126441 11.86623
## The BIC for this model 510.7587
```

**Part B:** Now we want to fit the same model with change in distribution:

$$\text{Claims}_i = \beta_0 + \beta_1 \text{Holders}_i + \varepsilon_i, \quad i = 1, 2, \dots, n$$

Assume :  $\varepsilon_i \sim \text{Laplace}(0, \sigma^2)$ . Note that  $\beta_0, \beta_1 \in \mathbb{R}$  and  $\sigma \in \mathbb{R}^+$ .

- (i) Clearly write down the negative-log-likelihood function in R. Then use `optim` function to estimate MLE of  $\theta = (\beta_0, \beta_1, \sigma)$
- (ii) Calculate **Bayesian Information Criterion** (BIC) for the model.

```
## Optimal parameters are 5.084375 0.1166253 2.863707
## The BIC for this model 498.687
```

**Part C:** We want to fit the following models:

$$\text{Claims}_i \sim \text{LogNormal}(\mu_i, \sigma^2), \text{ where}$$

$$\mu_i = \beta_0 + \beta_1 \log(\text{Holders}_i), \quad i = 1, 2, \dots, n$$

Note that  $\beta_0, \beta_1 \in \mathbb{R}$  and  $\sigma \in \mathbb{R}^+$ .

- (i) Clearly write down the negative-log-likelihood function in **R**. Then use **optim** function to estimate MLE of  $\theta = (\alpha, \beta, \sigma)$
- (ii) Calculate **Bayesian Information Criterion** (BIC) for the model.

Note that we have one point in our data set where Claims=0. Since the support of Lognormal distribution is  $(0, \infty)$ , we remove this point.

```
## Optimal parameters are 2.639779 0.001472126 0.8229641
## The BIC for this model 568.0199
```

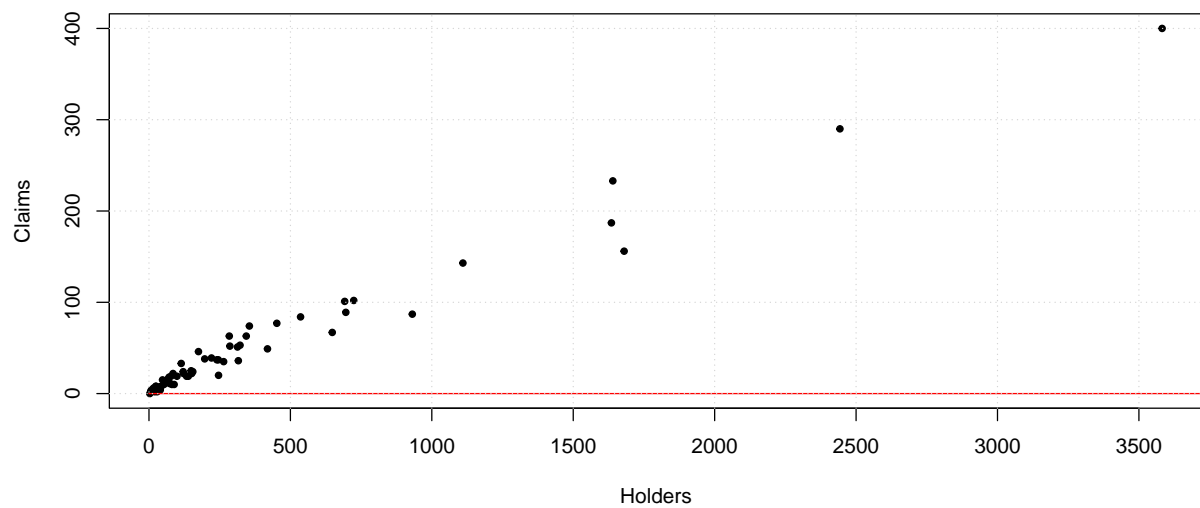

Part D: We want to fit the following models:

$$\text{Claims}_i \sim \text{Gamma}(\alpha_i, \sigma), \text{ where}$$

$$\log(\alpha_i) = \beta_0 + \beta_1 \log(\text{Holders}_i), \quad i = 1, 2, \dots, n$$

**Error in this**

```
## Optimal parameters are 0 0 49.23438
## The BIC for this model 639.2404
```

(iii) Compare the BIC of all three models

## Problem 5: Computational Finance - Modelling Stock prices

Following piece of code download the prices of TCS since 2007

```

Plot the adjusted close value of Nifty50

## Log-Return

We calculate the daily log-return, where log-return is defined as

$$r_t = \log(P_t) - \log(P_{t-1}) = \Delta \log(P_t),$$

where  $P_t$  is the closing price of the stock on  $t^{th}$  day.

- Consider the following model:

$$r_t^{TCS} = \alpha + \beta r_t^{Nifty} + \varepsilon,$$

where  $\mathbb{E}(\varepsilon) = 0$  and  $\text{Var}(\varepsilon) = \sigma^2$ .

1. Estimate the parameters of the models  $\theta = (\alpha, \beta, \sigma)$  using the method of moments type plug-in estimator discussed in the class.

**## Optimal parameters are 0.0004611205 0.7436972 0.01618653**

2. Estimate the parameters using the `lm` built-in function of R. Note that `lm` using the OLS method.

**## Optimal parameters are 0.0004611205 0.7436972 0.01618873**

3. Fill-up the following table

Parameters	Method of Moments	OLS
$\alpha$	0.0004611214	0.0004611214
$\beta$	0.7436967	0.7436967
$\sigma$	0.01618653	0.01618873

4. If the current value of Nifty is 18000 and it goes up to 18200. The current value of TCS is Rs. 3200/-. How much you can expect TCS price to go up?

**## New TCS price would be expected to be Rs. 3227.893**
